NOVATEN® Synthetic Tendon

The selection criteria for the size of the tendon graft to be implanted is in relation to the weight of the animal, the level of activity and to be compatible with the bone size.

As an indication:

- NOVATEN® 4000 fits into a 3,0 mm tunnel
- NOVATEN® 8000 fits into a 3,6 mm tunnel

THE CHOICE OF THE TENDON DEPENDS ON ANIMAL’S WEIGHT AND ACTIVITY

NOVETECH SURGERY® offers a full range of synthetic ligaments and tendons. Designed specifically for veterinary use, our products are minimally invasive and reflect the original native ligament or tendon we are replacing or reinforcing.

For the Quadriceps Tendon Reconstruction, we provide two sizes of tendon. Each has an approximate resistance in Newtons:

- NOVATEN® 4000: 4380 N
- NOVATEN® 8000: 8200 N

We use the only one Medical Grade UHMPWE Fibre in the world to guarantee you the best resistance and proven biocompatibility.

Used in millions of patients, its high softness enables it to reduce inflammatory reaction, irritation and thus accelerating recovery.
MANAGEMENT OF PATELLAR TENDON DISRUPTION IN CANINE PATIENTS USING A SYNTHETIC TENDON

Developed with DMV Philippe Buttin, Formation ECVS
Referral Activity in the Alps, France

STEP 1: Surgical approach
STEP 2: Tunnel Preparation
STEP 3: NOVATEN® / Patellar tendon Sutures
STEP 4: Passage of the prosthesis & Tensioning
STEP 5: Calcaneum Fixation
STEP 6: Post-operative
STEP 1

Perform a cranio-medial approach of the knee, starting distally at the tibial tuberosity and extend proximally above the patella. Medial Arthrotomy. Dissect the Patellar tendon to isolate it, from its enthesis to the musculotendinous junction. Debride the scar tissues on the lesion to keep healthy tissue.

STEP 2

The first bone tunnel is made from the insertion of the patellar tendon on the tibial tuberosity caudo-distally. Drill with a K wire and then over drill with the cannulated drill depending on which size implant is chosen.

For the NOVATEN® 8000, a 2 mm K wire is used for a 3.6 mm cannulated drill bit.

For a NOVATEN® 4000, a 1 mm K wire is used for a 3 mm cannulated drill bit.

The second tunnel is made perpendicular to the first one (a few millimetres distally to the exit of the first hole) using the same process (K-wire and Cannulated drill bit). Drill from the medial aspect to the lateral side of the tibia. This second tunnel is possible only if the bone is large enough to support it to avoid any risk of fracture.

The tunnel where you place the screw has to be pre-tapped.
STEP 3

Identify where the tendon lesion, rupture or avulsion of the enthesis or the musculotendinous junction is.

Make a longitudinal incision of the proximal end of the tendon over half its diameter from the musculotendinous junction to the site of rupture. This incision can be made on the dorsal side of the tendon in order to protect the sutures from friction with the skin caused by friction. The length of the Novaten® interface / tendon and the number of sutures made will determine the strength of the overall procedure.

Insert the Novaten® into the space left by the tendon incision. Stabilize the Novaten® with single sutures spaced 5 mm apart to sandwich it inside the Patellar tendon to the site of injury (site of rupture at the level of the body of the tendon). Polypropylene thread 2: 0 to 0 (3 to 3.5 metric) is used depending on the patient’s template. The use of UHMWPE wire is considered superior for tear resistance. NB: In the case of a rupture at the junction musculotendinous, it is possible to ascend proximally on the fascia of the muscle, then to insert the tendon in the distal tendinous space.

In the case of a rupture at the level of the enthesis the Novaten® traverses the whole of the tendon proximo-distally.

A Kessler suture or a «three loop Pulley» suture can be made to consolidate the join between both ends of the tendon when the affixation of the two tendon ends is possible. Once the suture is done, protect the prothesis with a compress soaked in saline so to limit the risks of contaminations.
STEP 4

The Novaten® synthetic tendon is passed through the first tunnel and the second perpendicular tunnel. It is then tensioned so it will function biomechanically and allow you to find the optimal length.

For the graft placement: insert the passing tube in the first tunnel and place the bendywire through the tube exiting proximally. Put the Novaten® ends into the bendy wire and pull through. Use the same technique for the second perpendicular tunnel so that the wire exits medially on the tibial.

Use a curved Kocher forceps to pull the tendon between the two tunnels. When the correct position is you can quickly lock the forceps on the medial side of the calcaneus to prevent the slipping of the implant back through the tunnel while you select the screw.

A functional check is made before the final fixation of the prosthesis. If the tension is not satisfactory, adjust by sliding the Novaten® in one direction or the other.
STEP 5

Measure the depth of the perpendicular tunnel and choose a screw that will be bicortical for a better fixation for the implant.

Insert the screw, guided a 1 mm K-wire to beyond the cortex. This allows during the second cortical passage to avoid a fracture. Use the cannulated screwdriver over the 1mm guide wire to insert the screw. Prefer a Ratchet screwdriver to preserve the axis of the screw during insertion and to avoid a deviation which may lead to fracture.

If you did not perform perpendicular tunnel, insert the crew through the main tunnel in the tibial tuberosity.
STEP 6

The use of Novaten® avoids having to use an external fixator.

A splint bandage is still recommended for 4 to 6 weeks. Or possibly a resin on particularly active dogs. A return to progressive exercise is recommended for 1 month after removal of the bandage. Physiotherapy is recommended.
Improved Resistance - Improved Biocompatibility - Larger space for suturing - Less Invasive - Easier fixation by interference screw

NEW IMPLANT - NOVATEN®

INSTRUMENTATION
A complete instrumentation kit is available for general ligamentoplasty using NOVATEN® or NOVALIG®.

INTERFERENCE SCREW

Diam. 4,0mm * Length 13mm
Diam. 4,5mm * Length 15mm
Diam. 4,5mm * Length 20mm
Diam. 5,0mm * Length 15mm
Diam. 5,0mm * Length 20mm

SUTURE - FIBER TECH
We recommend the use of FIBER TECH to suture the implant to the defect tendon. It will enable a stronger & immediate biomechanical fixation of the implants.

One canulated screwdriver for all size of screws
NOVETECH SURGERY® provides to the veterinarians a range of synthetic reinforcement systems for soft tissues based on years of experience.

In addition of the implants themselves, NOVETECH SURGERY® offers fixation systems as well as their instruments and power tools.

Join the Referents Clinicians Committee by adhering to the NOVETECH SURGERY® Scientific Charter.

This will give you access to a new range of Techniques, Scientifics Researches, Publications, Conferences, or Trainings on the future of Joint Surgery.
